Abstract

A grouted connection (GC) is a hybrid connection which joins two telescoped steel tubes by filling the annulus between the steel tubes with grout. GCs are frequently used to enable a force fitted connection between piles and substructure of offshore wind turbines. At latticed substructures this connection is located at mudline level in wet ambient conditions (AC). Nowadays special grout materials are used to achieve not only best mechanical properties but also a good performance during grouting in offshore conditions.

To reduce production costs the use of ordinary portland cement (OPC) is investigated as an alternative filling material within this paper. OPC has a much lower tendency to segregate, as there are no aggregates added. This leads to more simplified, stable and cheaper production processes offshore. Further focus is put on the failure mode of OPC filled GCs in submerged conditions.

For an appropriate use of OPC offshore a feasible mechanical performance needs to be ensured. Investigating this, small and large-scale laboratory tests were performed at Leibniz Universität Hannover. Using the experimental test setup of previous investigations for special high performance grouts (HPG) [1, 2], enables a direct comparison of HPG and OPC. Documenting liquid and solid OPC properties, like slump flow and compressive strength confirms a stable material quality. Small-scale ULS-tests showed significantly lower ULS-capacities and a more brittle failing process compared to HPG. Large-scale tests confirmed the observed failure mechanisms of Schaumann and Raba for OPC filled GCs in submerged conditions [3]. Carried out tests showed significant influence of grout material and confirmed influence of grout annulus size on fatigue capacity.

Keywords: Grouted Connection; Ordinary Portland Cement; Axial Loading; Fatigue; Submerged.

1. Introduction

A grouted connection (GC) is a composite connection of two steel tubes with different diameter. A smaller steel tube (pile) is plugged into a steel tube with larger diameter (sleeve). The annulus between these steel tubes is filled with an offshore specific grout material. To ensure a distinct interlocking, the steel surfaces in direction of the annulus are profiled with weld beads (shear keys) (cf. Fig. 1).

This type of connection is used to realise a force fitted connection between foundation piles and typically lattice substructures of offshore wind turbines, such as the jacket shown in Fig. 1.

Wave and wind loading lead to bending moments at the tower base. These are transferred by axial force couples into the foundation piles. Consequently GCs in lattice substructures are predominantly loaded by variable axial forces. Inside the connection the axial forces lead to concentrated compressive stresses ($\sigma_{\text{strut}}$) between two opposing shear keys. Depending on the shear keys position different strut inclination angles $\alpha$ occur; see Fig. 1. The radial load transfer results in tangential stresses ($\sigma_{\text{tangential}}$) in circumferential direction.
The previously described load bearing behaviour can lead to two major degradation mechanisms. On the one hand, shear cracking can occur along the compression struts (cf. Fig. 2). On the other hand, shear keys cause local stress concentrations in the grout material which can lead to local crushing. In dry ambient conditions the crushed material leads to a more homogenous load distribution at the shear keys and thereby a lower stress concentration. In connections with submerged ambient conditions (AC), water can enter the grout annulus by local cracks and bond loss gaps in interfaces [3]. Variable loading causes a pumping effect in cracks and interfaces. At the shear keys locally crushed material is flushed out of the connection. Consequently, step by step the pile is pushing through the grout. Fig. 2 shows a grouted connection after 200’000 load cycles and voids resulting from washed out grout material around the shear keys. Connection failure occurs over a large amount of load cycles.

Design methods for axially loaded GCs are only validated for a defined amount of geometrical and mechanical parameters as well as dry ambient conditions (cf. [4] and [3]). Thus, the research project ‘GROWup’ was realised at Leibniz Universität Hannover to investigate large grout annuli, HPG and OPC under realistic submerged AC. This paper focuses on the load bearing behaviour of OPC filled GCs as alternative for high performance grouts.

2. Grout material

Different OPCs were tested for material strength, hydration heat development, tendency to crack and shrinkage by the Institute of Building Material Science (LUH) [10]. Holcim Aqua4 (CEM III/B 42.5 LLH/SR/NA) showed most suitable material properties for its use in offshore conditions.

In order to document the OPC’s material characteristics, samples for cube and prism strength were taken in parallel with the grouting process of the GC specimens.

In contrast to offshore installations the grouting process of the presented tests occurred in ideal laboratory conditions. After 24 hours of hardening the specimens were stored in submerged condition. With 28 days of hardening the following material parameters were assessed:

\[
\begin{align*}
 f_c &= 60 \text{ MPa} \\
 E_{\text{stat}} &= 17'250 \text{ MPa} \\
 E_{\text{dyn}} &= 19'900 \text{ MPa}
\end{align*}
\]

3. Small-scale tests

3.1. Test set-up

Within the research project ‘GROWup’ a small-scale test set-up was developed to enable
submerged AC. To ensure reproducibility the same test rigs and specimen dimensions from previous investigations with high performance grout (BASF Masterflow 9500, $f_{cu} = 144.1$ MPa and Densit Ducorit S2, $f_{cu} = 116.3$ MPa) were used for OPC.

A cyclic compression-compression load in axial direction was generated by a servo-hydraulic press. Bending moments due to eccentricities were avoided by an axial hinge in the test rig.

### 3.2. Ultimate Limit State (ULS)

Within the ULS-tests a quasi-static load was increased until a maximum axial displacement of $u_{\text{max}} \approx 8$ mm was reached.

Fig. 4 shows the load-displacement behaviour due to quasi static loading. At the beginning of the ULS-tests initial crushing occurred at a low loading (marked with red color). After this initial crushing, which was observed for all small-scale ULS-tests with OPC, the specimens acted linear elastic until $F_{\text{elast}}$ was reached. With $F_{\text{elast}}$ a non-linear plastic behavior of the specimen started with significant loss of stiffness. Exceeding $F_{\text{ULS}}$ a stable post-failing behaviour began.

Comparing the ULS-failure of Holcim Aqua4 and Densit Ducorit S2 (cf. Fig. 5), shows a more brittle behaviour of a GC with OPC.

$$\frac{F_{\text{elast}}}{F_{\text{ULS}}} = 1:1.2 \quad (\text{Holcim Aqua4})$$

$$\frac{F_{\text{elast}}}{F_{\text{ULS}}} = 1:1.4 \quad (\text{Densit Ducorit S2})$$

Besides a more brittle behaviour, the ultimate strength of GCs with OPC was significantly lower than expected from the material strength ratio of Holcim Aqua4 and Densit Ducorit S2 [10].

$F_{\text{ULS}}$: 140kN / 543kN $\approx$ 1:4

$f_c$: 60MPA / 118MPa $\approx$ 1:2

One reason might be the lower interlocking inside the cracks, as OPC has no aggregates added. When it comes to cracking a lower remaining connection strength is left.
behaviour of OPC. Especially the left side depicts a huge amount of diffuse cracks beside the typical shear cracks along the compression struts (white), spread all over the grout layer. Compared to Fig. 7 cracking OPC leads to sharpedged, clean fragments. This effect results from the lack of aggregates and thereby a very homogenous material.

![Fig. 6. Dismantled specimen with Holcim Aqua4 (F_{\text{max}} = 50\% F_{\text{ULS}}, f = 5Hz, AC: wet)](image)

**3.3. Fatigue Limit State (FLS)**

In comparison to the ULS-tests the fatigue tests are realized under dry and submerged AC. According to the ULS strength constant amplitudes of 0.2 F_{ULS} and 0.5 F_{ULS} were applied until failure. Dry tests showed significantly higher fatigue strength than tests under submerged AC (cf. Fig. 8). The fatigue strength shows huge scatter and no feasible coherences to generate an S-N-curve for this kind of GC. Therefore, more tests are needed to be statistically secured. Scale effects might have a huge influence on the results.

![Fig. 8. S-N-curve of small-scale tests (Geom 1)](image)

Analyzing the failure mode showed good accordances to GCs filled with high performance grout [8]. Flushing of locally crushed OPC and shear failure along the compression struts was observed.

**4. Large-scale tests**

**4.4. Test set-up**

A further investigation of ‘GROWup’ was the development of a large-scale test set-up for submerged ambient conditions (cf. Fig. 11) to reduce scale effects and install more detailed measurement systems. Thereby two different test specimens G1 and G2 with large grout annulus were investigated. Same test set-up was used for OPC to have a direct reproducibility between HPG and OPC.

![Fig. 9. Test setup of the large scale GC (submerged ambient condition)](image)
Different to common fatigue tests a stepwise constant amplitude of compression-compression loading was applied. With each 100’000 load cycles (one step) the cyclic axial load was increased by 250 kN. A stepwise increasing fatigue test approximates the state of fatigue failure, as initial damage from lower load stages cannot be quantified. However different load stages can be analysed with a low amount of tests. The damage of the GC was defined by the relative axial displacement between pile and sleeve.

4.5. Results

The displacement behaviour of specimen G1 is shown in Fig.10. After a linear elastic behaviour (no degradation) in the first load step, a small degradation of 0.4 mm axial relative displacement occurred in load step 2 ($2\times10^6$ mm/cycle). Further load increase to 750 kN led to a significant degradation growth of 1.7 mm in load step 3 ($1.7\times10^7$ mm/cycle); the degradation had quadruplicated. As guidelines do not suggest termination criterions (TC) for fatigue tests of GC these tests were terminated at relative displacements between pile and sleeve of $u \approx 2$ mm and a continuous degradation per load cycle (cf. Fig.10). Executing the test procedure at an earlier stage of degradation compared to previous investigations of Schaumann and Raba (terminated at $u \approx 25$ mm) [2] should give information on the chronology of compression strut failure and local crushing on fatigue damage initiation.

Specimen G2 with a smaller grout annulus of $t_g = 81.5$ mm, had more then twice the fatigue capacity of the specimen G1. Approximatly the same amount of displacement and thereby degradation was reached finishing load step 7 (1750 kN). Detailed data is shown in Fig. 11. Compared to G1 the linear elastic behaviour enlarged to load step 4 in G2. In load step 5 and 6 small degradative effects were observed. However no continuous degradation occurred. In load step 7 the degradation switched to a continuous pushing through. The test was terminated.

![Fig. 10. Relative axial displacement $u$ between pile and sleeve of specimen G1](image)

![Fig. 11. Relative axial displacement $u$ between pile and sleeve of specimen G2](image)

Exemplarily the dismantled specimen of G1 is shown in Fig. 12. Opening the tested specimens, showed a mostly intact grout annulus, with two cracks in horizontal direction at the top and bottom end off the shear key area (sleeve side). Additionally, local grout crushing at the pile’s shear keys occurred. In addition some micro cracks were observed scattered over the grout layer. Their influence on the fatigue capacity is assumed to be negligible. The measured relative axial displacement (cf. Fig.10) coincides with the void area at the shear keys. Concludingly, local crushing at the shear keys is
decisive for the fatigue capacity of GC filled with OPC under submerged conditions.

A quantitative comparison of OPC and HPG for GCs is not possible from the tests carried out. Different to the tests with OPC previous test configurations were performed with load steps of 1 MN. Despite different load step sizes, comparing same amounts of degradation per cycle, a ratio of fatigue capacity between OPC and HPC is prognosed.

Table 1. Comparison of fatigue capacity of GC with Densit Ducorit and Holcim Aqua4

By reference to Table 1 the fatigue strength ratio $FSR \approx 2$ is approximately the same as the material strength ratio $MSR \approx 2$.

5. Conclusion and outlook

In this paper results of small and large-scale tests of axially loaded grouted connections with ordinary portland cement (OPC) were presented. Thereby the load-bearing behaviour under quasi-static and cyclic axial loading was analysed and compared to grouted connections with high performance grouts (HPG).

Compared to HPG small-scale ULS-tests with OPC showed a significantly reduced ultimate limit strength ($F_{ULS,OPC}/F_{ULS,HPG} \approx 1:4$) thereby initial crushing and a more brittle connection failure was identified. Reasons for this might be reduced interlocking of crack surfaces due to missing aggregates and a significantly lower material strength of the grout material.

The fatigue behaviour of OPC filled GCs under axial cyclic compression loading was similar to HPG filled GCs. The small amount of realised large-scale tests showed tendentially proportional correlation between material strength and connection strength. The next step would be to develop a generic ultimate limit criterion for grouted connections under submerged conditions. Therefore, further investigations are needed. On the one hand, the degradation development under large axial displacements has to be investigated due to expected nonlinear damage progression. On the other hand, the degradation leads to stiffness loss in the jacket chords and thereby can influence the global load-bearing behaviour of the total substructure.

On basis of the tests carried out OPC seems to be a suitable alternative to high performance grouts. Due to reduced connection strength the grout length has to be increased and more shear keys are needed to achieve comparable fatigue resistances.

6. Acknowledgement

The presented results were achieved within the research project ‘GROWup - Grouted Joints for Offshore Wind Energy Converters under reversed axial loadings and upscaled thicknesses’ funded by the German Federal Ministry for Economic Affairs and Energy (BMWi, funding sign: 0325290). The research partners were Institute for Steel Construction and Institute of Building Material Science, both at Leibniz Universität Hannover, Germany.
The authors thank the BMWi for funding and all accompanying industry project partners (DNV GL, Senvion SE, Siemens Wind Power, Wilke & Schiele Consulting GmbH) for their support. Additionally, the authors thank the material manufacturers for their support. Concluding thanks go to Prof. Lohaus and his team from the Institute of Building Material Science for an excellent project collaboration.
