Abstract

Pirarucu (Arapaima gigas Schinz) farming has been encouraged and, among meat preservation techniques, the salting process is a relatively simple and low-cost method. The objective of this work was to study the sodium chloride diffusion kinetics in Pirarucu during wet salting. Limited volumes of brine (20% w/w) were employed with wet salting assays carried at 3, 4 and 5 brine/muscle ratios, and brine temperatures of 10, 15 and 20 °C. The analytical solution of Fick’s second law considering one-dimensional diffusion through an infinite slab in contact with a well-stirred solution of limited volume was used to calculate the effective salt diffusion coefficients. Salt diffusivities in muscle were found to be in the range of 2.07 and 8.80 × 10^-10 m^2/s. The wet salting of Pirarucu is greatly influenced by temperature and by the brine/muscle ratio by volume.

Keywords: Pirarucu; Arapaima gigas Schinz; salt diffusion coefficients; brine.
1. Introduction

The pirarucu (Arapaima gigas Schinz) is one of the largest freshwater fish in the world, reaching approximately 2 to 3 meters in length and up to 200kg in weight in its natural habitat. The fish inhabits the Amazon River basin in South America and is one of the five most widely cultivated and marketed species in the region [1, 2, 3, 4]. It is economically and ecologically important to the riverside population due to its high commercial and nutritional value [3, 5]. Due to its great adaptability, high market value, good sensory characteristics, expressive size and rapid development, the pirarucu has been a focus of several studies, mainly in relation to its captive breeding [6].

The increase in the pirarucu farming in aquaculture production systems has highlighted the economic significance of this species in recent years, mainly due to its nutritional quality. However, its marketing and consumption throughout the year faces some barriers due to the many changes occurring in the product because of enzyme and microbiological activities, which can affect the flavor, odor, color and texture and lead to rapid deterioration, resulting in fish of lower quality [7, 8].

Studies on shelf-life of food products depend on the knowledge of internal and external characteristics that can affect the speed of deterioration, such as packaging technologies, storage conditions, formulation and conservation among others [8]. Salting is one of the oldest food conservation processes [9, 10]. The concentration of sodium chloride influences the technological properties of the food, such as water retention capacity, viscosity, texture, emulsification, influences the properties of proteins and promotes sensory acceptance [11, 12].

Salting is a good alternative for producing processed food because it is a relatively simple, low-cost technique and can be carried out in places with little infrastructure. Brining is a specific process of osmotic dehydration that is conducted by immersing the product in concentrated saline solution [13]. In this operation, two main mass transfer processes occur. The water migrates from the meat to the brine and solutes from the brine transfer to the meat. Consequently, changes in the composition of solids produce a decrease in the amount of water available for degradation reactions by enzymes and microorganisms [14, 15].

The diffusion of salt in meats and meat products has been the objective of some studies [16]. Diffusion is an important mass transfer phenomenon, responsible for the transport of sodium and chloride [17]. The mass transfer between the brine and the product is usually controlled by the diffusion rate of the solutes. Diffusion rates are calculated using solution diffusion coefficients for solids [18]. Food and foodstuffs present irregular shapes and have regions of different compositions that make the mathematical modeling difficult and some alternatives should be considered to deal with the heterogeneity of materials [16, 19, 20].
Water loss and absorption of solids during osmotic dehydration have been modeled using Fick’s second law. Some studies use analytical solutions for transfer of one-dimensional mass based on laboratory studies carried out with a great excess of agitated solution, in order to ensure a variation in the composition of the solution and simplify the calculations involved [21]. To determine the effective diffusivity of salt in caiman meat, Romanelli & Felício [22] used the same approach. However, the management of large volumes of solution is an obstacle to the process at an industrial scale, leading to an increase in production costs.

The knowledge of the diffusion rates is important, as it allows the correct determination of the necessary processing time, having control over the exact final concentration of salt and its distribution in the product. Several articles have been published on mass transfer and diffusion of salt in meat and fish products [23, 24]. So, the aim of this study was to evaluate the proximate composition of the pirarucu raw material and investigate the sodium chloride diffusion kinetics in pirarucu muscle during wet salting.

2. Materials and Methods

This study focused on the sodium chloride diffusion in pirarucu muscle during the wet salting process using a limited volume of brine (20% w/w). The experiments were developed and done in the meat and meat products laboratory of the Department of Engineering and Food Technology of the Sao Paulo State University – UNESP-IBILCE.

The material used in this study consisted of a frozen Pirarucu fillets (Arapaima gigas Schinz) purchased from a single supplier, in a local supermarket in the city of Manaus (Brazil). The fillets were transported to UNESP-IBILCE (São José do Rio Preto, Brazil), stored under freezing and thawed under refrigeration temperature for 24 hours for evaluation of its physical characteristics, such as size and weight, and also the proximate composition, before salting. Moisture, ash and protein contents were determined according to the AOAC [25] method. The lipid content was determined, following the method described by Bligh & Dyer [26].

Sodium chloride solution was used as the osmotic agent. The sodium chloride used was of food grade, the other chemical compounds used for the determinations of sodium chloride, proteins and lipids were of analytical grade.

Experiments were carried out with a brine concentration of 20% (w/w), at temperatures of 10, 15 and 20 °C and volume ratios of brine/muscle (V_L / V_S) of 3, 4 and 5.

Fillet densities before salting and at different periods after salting were measured according to the liquid displacement method [13]. Brine densities were measured by means of a pycnometer at 25 °C.
Fillets were weighed and placed inside flasks of 500 ml containing brine at a pre-determined volume, temperature and salt concentration. The flasks were then maintained in a refrigerated orbital agitator, being removed at different time intervals, when the brine was drained and weighed and the fillets were dried with absorbent paper, weighed and ground. Two aliquots for salt content, estimated as the ash contents in a muffle furnace at 550 °C. Two aliquots of brine were taken to measure the salt content. The salt content was obtained according to the Mohr method [27].

The governing equation for the unsteady-state one-dimensional diffusion in a plane slab was given by Fick's second law, also called the diffusion equation, and the analytical solution of the stated problem was given by Crank [28] as:

\[
\frac{M_t}{M_\infty} = 1 - \sum_{n=1}^{\infty} \frac{2\alpha (1 + \alpha)}{1 + \alpha + \alpha^2 q_n^2} \exp\left(-\frac{D_{eff} q_n^2 t}{L^2}\right)
\]

(1)

where \( \frac{M_t}{M_\infty} \) is the total amount of solute in the solid at time \( t \), \( M_\infty \) is the corresponding quantity at equilibrium, \( L \) is half of the slab thickness and \( q_n \) are the non zero positive roots of the equation

\[
\tan q_n = -\alpha q_n
\]

(2)

In order to adjust equation (1) to the experimental data and obtain the effective diffusivity values, parameters \( m \), \( \alpha \), and \( q_n \) were determined according to Telis et al. [13].

The effective diffusivities were obtained by a non-linear adjustment of the first six terms of the series corresponding to equation (1), which was performed using the Statistica software (StatSoft Inc., V.7.0).

3. Results and discussion

The proximate composition of Pirarucu muscle is shown in Table 1. Similar results were found by Martins et al. [29], when analyzing the proximal composition of pirarucu muscle.
Table 1. Proximal composition of the Pirarucu muscle (n=3).

Table 2 shows that the brine/muscle ratio has a low effect, since effective diffusivities were very similar for the different ratios at the same temperatures. Similar behavior was observed by Medina-Vivanco et al. [30] when they studied tilapia muscle.

Effective diffusivities increased with increasing temperatures (Table 2) for all brine/muscle ratios. Similar results were observed by Telis et al. [13] who studied salting diffusivities in caiman muscle. Low temperatures are recommended because fish is a very perishable food. Brás & Costa [31] used salting temperatures from 12 °C to 18 °C for salting different fishes. According to Chiralt et al. [32], higher temperatures not only affect the rate of diffusion.
phenomenon but also may affect the viscoelastic properties of the solid matrix, with a softening of the structure accompanying the temperature increase. An additional effect in salt gain rates could arise from the reduction in brine viscosity at higher temperatures.

Salted fish products have a long shelf life due to their low water activity and the flora selection that a high salt content media implies [31].

4. Conclusions
Salt effective diffusion coefficients are in the range from $2.07 \times 10^{-10}$ to $8.80 \times 10^{-10} \text{ m}^2/\text{s}$.

The wet salting process of pirarucu is greatly influenced by temperature: the higher the temperature in the wet salting process, the higher the effective diffusion coefficients; and, to a lesser extent, by the brine/muscle volume ratio though lower temperatures are better because fish is a perishable food.
